Renewable Electricity Futures: An Investigation of 30-90% Renewable Power

Stanford Energy Forum

November 2012

A U.S. DOE-sponsored collaboration among more than 110 individuals from 35 organizations.

NREL is a national laboratory of the U.S. Department of Energy, Office of Energy Efficiency and Renewable Energy, operated by the Alliance for Sustainable Energy, LLC.
To what extent can renewable energy technologies commercially available today meet the U.S. electricity demand over the next several decades?
Renewable Electricity Futures Introduction

- RE Futures is an analysis of the U.S. electric sector focused on 2050 that explores:
  1. Whether the U.S. power system can supply electricity to meet customer demand with high levels of renewable electricity, including variable wind and solar generation.
  2. Grid integration using models with unprecedented geographic and time resolution for the contiguous U.S.
  3. Synergies, constraints, and operational issues associated with a transformation of the U.S. electric sector.
Renewable Electricity Futures Report

Volume 1: Exploration of High-Penetration Renewable Electricity Futures
Volume 2: Renewable Electricity Generation and Storage Technologies
Volume 3: End-Use Electricity Demand

REF is a U.S. DOE-sponsored collaboration with more than 110 contributors from 35 organizations including national laboratories, industry, universities, and non-governmental organizations.

General Assumptions

- **Energy Efficiency:** Most of the scenarios assumed significant adoption of energy efficiency (including electricity) measures in the residential, commercial, and industrial sectors.

- **Transportation:** Most of the scenarios assumed a shift of some transportation energy away from petroleum and toward electricity in the form of plug-in hybrid or electric vehicles, partially offsetting the electricity efficiency advances that were considered.

- **Grid Flexibility:** Most scenarios assumed improvements in electric system operations to enhance flexibility in both electricity generation and end-use demand, helping to enable more efficient integration of variable-output renewable electricity generation.

- **Transmission:** Most scenarios expanded the transmission infrastructure and access to existing transmission capacity to support renewable energy deployment. Distribution-level upgrades were not considered.

- **Siting and Permitting:** Most scenarios assumed project siting and permitting regimes that allow renewable electricity development and transmission expansion with standard land-use exclusions.
Renewable Resources and Technologies

Biopower ~100 GW
- Stand-alone
- Cofired with coal

Hydropower ~200 GW
- Run-of-river

Solar CSP ~37,000 GW
- Trough With thermal
- Tower storage

Solar PV ~80,000 GW
- Residential
- Commercial
- Utility-scale
  Rooftop PV ~700 GW

Geothermal ~36 GW
- Hydrothermal

Wind ~10,000 GW
- Onshore
- Offshore fixed-bottom

- Only currently commercial technologies were modeled (no EGS, ocean, floating wind) with incremental and evolutionary improvements.
- RE characteristics including location, technical resource potential, and grid output characteristics were considered.
Key Results
RE generation from technologies that are commercially available today, in combination with a more flexible electric system, is more than adequate to supply 80% of total U.S. electricity generation in 2050—while meeting electricity demand on an hourly basis in every region of the country.
Renewable generation resources could adequately supply 80% of total U.S. electricity generation in 2050 while balancing hourly supply and demand.
The abundance and diversity of RE resources can support multiple combinations of RE technologies to provide 80% generation by 2050.

- Technology deployment depends on scenario assumptions, but in all cases examined, RE resources existed to compensate for assumed variations in access to transmission, grid flexibility, resource availability, technology costs, and electricity demand.
- Constraints to transmission result in greater PV, offshore wind, and biopower deployment.
- Constraints to system flexibility result in greater dispatchable technology deployment, e.g., storage and CSP with thermal storage.
- Constraints to resource accessibility result in greater wind and solar deployment.

Low-Demand ranges encompass results for Technology Improvement and Constrained scenarios.
All regions of the country could contribute substantial renewable electricity supply in 2050

80% RE-ITI scenario
Actions to Accommodate Variable RETs

- **Lead public engagement, particularly for new transmission**
  - Planning requires continuous engagement of diverse stakeholders to facilitate public support for new transmission

- **Coordinate and integrate planning**
  - Reduced reserve requirements can be reflected in integrated plans for new transmission and generation

- **Improve system operations**
  - New transmission allows expanded access to diverse resources, through new locations and interconnections
  - Expanded access to diverse resources reduces variability and improves system operations through increased forecast accuracy
  - Improved forecast accuracy reduces reserve requirements for system flexibility

- **Expand access to diverse resources**

Cochran et al, NREL/TP-6A00-53730 April 2012
A more flexible electric power system is needed to enable electricity supply-demand balance with high levels of RE generation

*System flexibility can be increased using a broad portfolio of supply- and demand-side options, including:*

- Flexible generators (particularly natural gas)
- Dispatchable renewables (e.g., biopower, geothermal, CSP with storage and hydropower)
- Demand response (e.g., interruptible load)
- Controlled charging of electric vehicles
- Storage
- Curtailment
- Transmission
- Geospatial diversity of the variable resources to smooth output
- Coordinating bulk power system operations across wider areas
Electricity supply and demand can be balanced in every hour of the year in each region with 80% electricity from renewable resources*

*Full reliability analysis not conducted in RE Futures
System flexibility provided through increased ramping and startup-shutdown of conventional generators, particularly in low-demand periods.
Dispatchable renewable generators and storage provide system flexibility by shifting operation to periods of high net load

Dispatch of CSP with thermal storage in Western Interconnection (80% RE ITI)

Source: Denholm, ........ (2012)
80% RE is achievable with new Transmission or if new Tx is constrained.

- In most 80%-by-2050 RE scenarios, 110-190 million MW-miles of new transmission lines are added.
- AC-DC-AC interties are expanded to allow greater power transfer between asynchronous interconnects.
- However, 80% RE is achievable even when transmission is severely constrained (30 million MW-miles)—which leads to a greater reliance on local resources (e.g. PV, offshore wind).
- Annual transmission and interconnection investments in the 80%-by-2050 RE scenarios range from $5.7B-8.4B/year, which is within the range of recent total investor-owned utility transmission expenditures.
- High RE scenarios lead to greater transmission congestion, line usage, and transmission and distribution losses.
All regions of the country could contribute substantial renewable electricity supply in 2050 – especially when transmission is constrained.

Red arrows indicate magnitude and direction of change relative to the 80% RE-ITI scenario.
The abundance and diversity of RE resources can support multiple combinations of RE technologies to provide 80% generation by 2050.

Future (relative) RE technology cost and performance drives deployment toward different mix of technologies depending on commercial and technological maturity.

Ranges encompass results for (low-demand) Technology Improvement and Constrained scenarios.
High renewable electricity futures can result in deep reductions in electric sector greenhouse gas emissions and water use.

80% RE scenarios lead to:
- ~80% reduction in 2050 generation from both coal-fired and natural gas-fired sources
- ~80% reduction in 2050 GHG emissions (combustion-only and life cycle)
- ~50% reduction in electric sector water use
- Gross land use totaling <3% of contiguous U.S. area; other related impacts include visual, landscape, noise, habitat, and ecosystem concerns.

* USDA 2010, **Denholm & Margolis 2008
Incremental cost associated with high RE generation is comparable to published cost estimates of other clean energy scenarios

- Comparable to incremental cost for clean energy and low carbon scenarios evaluated by EIA and EPA
- Reflects replacement of existing generation plants with new generators and additional balancing requirements (combustion turbines, storage, and transmission) compared to baseline scenario (continued evolution of today’s conventional generation system)
- Assumptions reflect incremental or evolutionary improvements to currently commercial RE technologies; they do not reflect U.S. DOE activities to further lower these costs.

Source: Renewable Electricity Futures (2012)
Improvement in cost and performance of RE technologies is the most impactful lever for reducing the incremental cost

- Cost is less sensitive to the assumed electric system constraints (transmission, flexibility, RE resource access).
- Electricity prices in high RE scenarios are largely insensitive to projections for fossil fuel prices and fossil technology improvements.
- Lower RE generation levels result in lower incremental prices (e.g., 30% RE-ETI scenario shows no incremental cost relative to the baseline scenario).
- Cost figures do not reflect savings or investments associated with energy efficiency assumptions in the low-demand Baseline and 80% RE scenarios.
No insurmountable long-term constraints to RE technology manufacturing capacity, materials supply, or labor availability were identified.

- 80% RE generation in 2050 requires additions of ~20 GW/year in 2011-2020, ~30/GW/year in 2021-2040, and ~40 GW/year in 2041-2050 (higher under High-Demand scenario).
- These installation rates are higher than U.S. capacity additions in 2010 (7 GW) and 2009 (11 GW) and would place challenges on RE industries.
- Recent U.S. and worldwide growth demonstrate the scalability of RE industries.
- More informed siting practices and regulations can reduce industry scale-up challenges.
Renewables can meet 80% of High Demand

- Higher demand growth generally implies an increased need for new generation and transmission capacity in both the baseline and 80% RE scenarios.
- More renewable generation capacity, particularly wind and PV, is needed; it will result in greater industry scale-up and resource access challenges.
- Additional flexible supply- and demand-side capacity (e.g., storage, natural gas combustion turbine power plants, and interruptible load) is also needed.
- While higher demand growth shows greater increases in electricity prices, the direct incremental cost associated with high renewable generation levels decreases (the prices in baseline also increase).
- Cost-effectiveness of energy efficiency vs. supply-side options was not evaluated.
Summary of Key Results

• Renewable electricity generation from technologies that are commercially available today, in combination with a more flexible electric system, is more than adequate to supply 80% of total U.S. electricity generation in 2050—while meeting electricity demand on an hourly basis in every region of the country.

• Increased electric system flexibility, needed to enable electricity supply-demand balance with high levels of renewable generation, can come from a portfolio of supply- and demand-side options, including flexible conventional generation, grid storage, new transmission, more responsive loads, and changes in power system operations.

• The abundance and diversity of U.S. renewable energy resources can support multiple combinations of renewable technologies that result in deep reductions in electric sector greenhouse gas emissions and water use.

• The direct incremental cost associated with high renewable generation is comparable to published cost estimates of other clean energy scenarios. Improvement in the cost and performance of renewable technologies is the most impactful lever for reducing this incremental cost.
Future Work Needed

• A comprehensive cost-benefit analysis is necessary in order to better understand the economic and environmental implications of high renewable electricity futures relative to today’s electricity system. Today’s system is largely based on conventional technologies and alternative futures in which other sources of clean energy are deployed at scale.

• Further investigation of the more complete set of issues around all aspects of power system reliability is needed because RE Futures only partially explores the implications of high penetrations of renewable energy for system reliability.

• Improved understanding of the institutional challenges associated with the integration of high levels of renewable electricity, including development of market mechanisms that enable the emergence of flexible technology solutions and mitigate market risks for a range of stakeholders, including project developers, is important.

• Analysis of the role and implications of energy research and development activities in accelerating technology advancements and in broadening the portfolio of economically viable future renewable energy supply options and supply- and demand-side flexibility tools is essential.
Future work to address reliability of high RE scenarios

- What analysis is needed to demonstrate feasibility of high renewable electricity futures?
  - Capacity expansion with statistical treatment of resource adequacy
    - Seasonal/diurnal time scale
  - Production cost modeling of operation in future year to assess resource adequacy
    - Hourly time scale
    - Sub-hourly time scale
  - Auto Generation Control-level modeling to assure stable reaction to contingencies
    - Sub-minute time scale
  - Load flow and contingency analysis to assure recovery from transient disturbances
    - Sub-second time scale

  Done in REF

  Not done in REF
A future U.S. electricity system that is largely powered by renewable sources is possible, and further work is warranted to investigate this clean generation pathway.
